

Def gopher-massivetext():

massive text data to train model gopher.

subsumed by chinchilla → C4, Books, News, Github, wikipedia

- process steps:
1. keep English, de-duplication, train-test overlap
 2. quality filtering using manual rules (not classifier).
e.g., -80% words contain at least one alphabetic letter.
 3. use Google safe search for toxicity

Def llama():

Dataset for Llama:

1: common crawl: CC processed CCNet, classify references of wikipedia or not

2: C4 (more diverse, recall: rule-based filtering)

3: Github: kept ~~permissive~~ permissive license, filtering based on manual rules

4: wikipedia: Jan-Aug 2022, 20 languages, manual filtering

5: project ~~gutenberg~~ gutenberg and Books 3

6: ArXiv: removed comments, inline expanded (from the pile)
marcos, bibliography

7: stackexchange: 28 largest websites, sorted by answer score

Result: 1.2T tokens

Def refinedWebc):

- 1: point: web data is all you need
 - 2: HTML $\rightarrow$ Text, extract content (WARC instead of WET files)
 - 3: Filtering: Gopher rules, avoid ML-based filtering to avoid bias
 - 4: Fuzzy deduplication using MinHash over model-based $\rightarrow$ pos/neg classifier 5-grams
- Release 600B (out of 5T) tokens

FineWeb: ~~est~~

- standard CC processing
- 1: improved version of refinedweb
 - 2: 95 common crawl dumps
 - 3: url filtering, language ID, keep English
 - 4: Filtering: Gopher, C4, more manual rules.
 - 5: Fuzzy deduplication via Minhash.
 - 6: Anonymize email and public IP address

Result: 15T tokens

def dolma():

- common crawl $\Rightarrow$ web page
- The stack ^{repo} $\Leftrightarrow$ code, just like github
- C4 $\Leftrightarrow$ web pages, improve CC version
- Reddit $\Leftrightarrow$ social media
- arXiv $\Leftrightarrow$ STEM papers
- Project Gutenberg $\Leftrightarrow$ ebooks
- Wikipedia, Wikibooks $\Leftrightarrow$ encyclopedic

common crawl (processing steps $\Rightarrow$): FastText (classifier to identify language and only keeps English; 2) quality filtering, C4 rules, avoid model-based filtering
